

Juniper

JN0-351 Exam

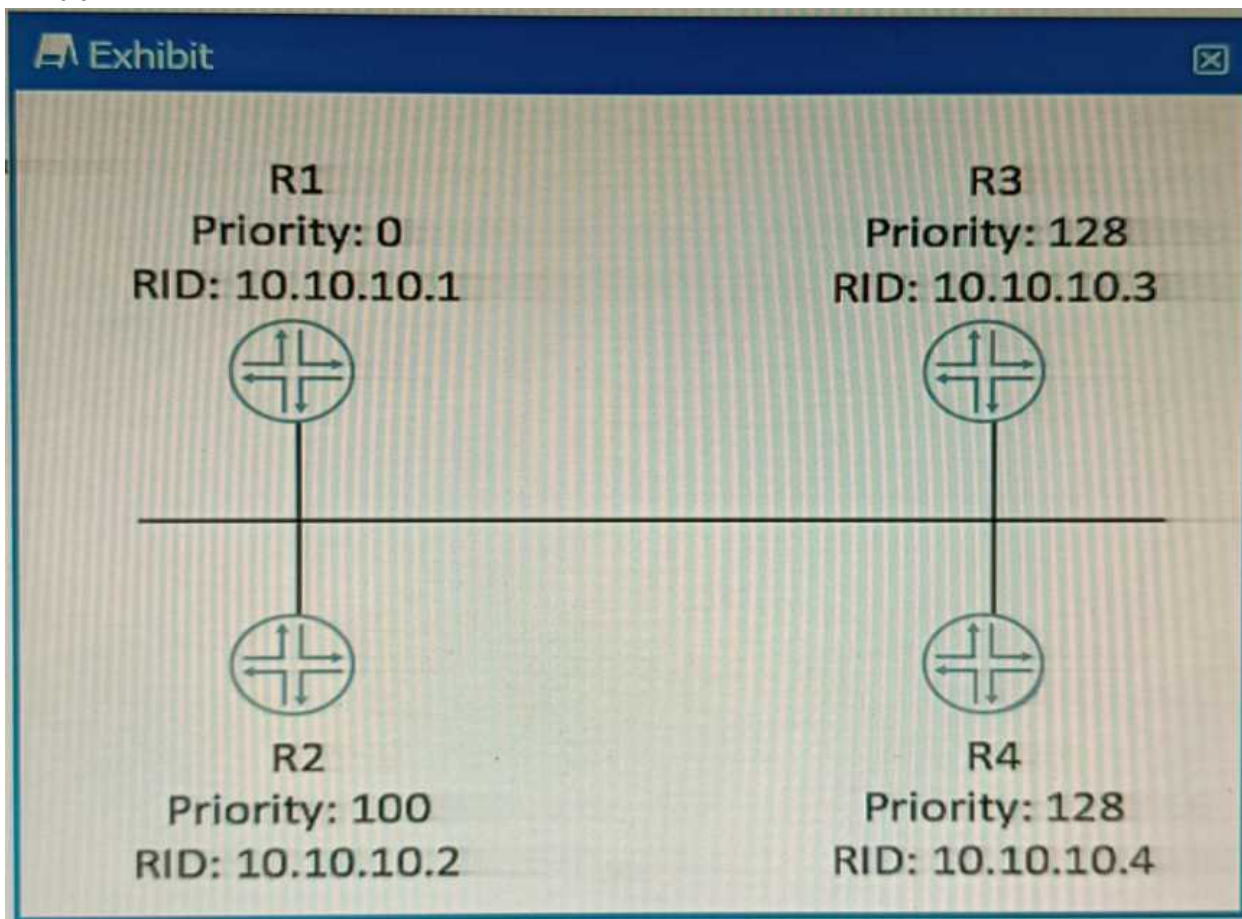

Enterprise Routing and Switching Specialist

Questions & Answers
Demo

Version: 4.0

Question: 1

Exhibit.

Which router will become the OSPF BDR if all routers are powered on at the same time?

- A. R4
- B. R1
- C. R3
- D. R2

Answer: A

Explanation:

OSPF DR/BDR election is a process that occurs on multi-access data links. It is intended to select two

OSPF nodes: one to be acting as the Designated Router (DR), and another to be acting as the Backup Designated Router (BDR). [The DR and BDR are responsible for generating network LSAs for the multi-access network and synchronizing the LSDB with other routers on the same network1.](#)

The DR/BDR election is based on two criteria: the OSPF priority and the router ID. The OSPF priority is a value between 0 and 255 that can be configured on each interface participating in OSPF. The default priority is 1. A priority of 0 means that the router will not participate in the election and will never become a DR or BDR. The router with the highest priority will become the DR, and the router with the second highest priority will become the BDR. If there is a tie in priority, then the router ID is used as a tie-breaker. The router ID is a 32-bit number that uniquely identifies each router in an OSPF domain. [It can be manually configured or automatically derived from the highest IP address on a loopback interface or any active interface2.](#)

In this scenario, all routers have the same priority of 1, so the router ID will determine the outcome of the election. The router IDs are shown in the exhibit as RID values. The highest RID belongs to R4 (10.10.10.4), so R4 will become the DR. The second highest RID belongs to R3 (10.10.10.3), so R3 will become the BDR.

tap                 up    up
vme                 up    down
```

What is the management IP address of the device shown in the exhibit?

- A. 10.210.20.233
- B. 172.23.12.100
- C. 128.0.0.1
- D. 172.23.11.10

Answer: B

Explanation:

The management IP address of a device is the IP address that is used to access the device for configuration and monitoring purposes. It is usually assigned to a dedicated management interface that is separate from the data interfaces. The management interface can be accessed via SSH, Telnet, HTTP, or other protocols.

In the exhibit, the list of interfaces and their statuses shows that the management interface is me0. This interface has an admin status of up, a protocol status of inet, a local address of 172.23.12.100/24, and a remote address of unspecified. This means that the me0 interface is active, has an IPv4 address assigned, and is not connected to another device.

Therefore, the management IP address of the device shown in the exhibit is 172.23.12.100.

Question: 3

Which three protocols support BFD? (Choose three.)

- A. RSTP
- B. BGP
- C. OSPF
- D. LACP
- F. FTP

Answer: BCD

Explanation:

BFD is a protocol that can be used to quickly detect failures in the forwarding path between two adjacent routers or switches. BFD can be integrated with various routing protocols and link aggregation protocols to provide faster convergence and fault recovery.

[According to the Juniper Networks documentation, the following protocols support BFD on Junos OS devices1:](#)

BGP: BFD can be used to monitor the connectivity between BGP peers and trigger a session reset if a failure is detected. [BFD can be configured for both internal and external BGP sessions, as well as for IPv4 and IPv6 address families2.](#)

OSPF: BFD can be used to monitor the connectivity between OSPF neighbors and trigger a state change if a failure is detected. [BFD can be configured for both OSPFv2 and OSPFv3 protocols, as well as for point-to-point and broadcast network types3.](#)

LACP: BFD can be used to monitor the connectivity between LACP members and trigger a link state change if a failure is detected. [BFD can be configured for both active and passive LACP modes, as well as for static and dynamic LAGs4.](#)

Other protocols that support BFD on Junos OS devices are:

IS-IS: BFD can be used to monitor the connectivity between IS-IS neighbors and trigger a state change if a failure is detected. BFD can be configured for both level 1 and level 2 IS-IS adjacencies, as well as for point-to-point and broadcast network types.

RIP: BFD can be used to monitor the connectivity between RIP neighbors and trigger a route update if a failure is detected. BFD can be configured for both RIP version 1 and version 2 protocols, as well as for IPv4 and IPv6 address families.

VRRP: BFD can be used to monitor the connectivity between VRRP routers and trigger a priority change if a failure is detected. BFD can be configured for both VRRP version 2 and version 3 protocols, as well as for IPv4 and IPv6 address families.

The protocols that do not support BFD on Junos OS devices are:

RSTP: RSTP is a spanning tree protocol that provides loop prevention and rapid convergence in layer 2 networks. RSTP does not use BFD to detect link failures, but relies on its own hello mechanism that sends BPDU packets every 2 seconds by default.

FTP: FTP is an application layer protocol that is used to transfer files between hosts over a TCP connection. FTP does not use BFD to detect connection failures, but relies on TCP's own retransmission and timeout mechanisms.

Question: 4

Exhibit.

```

user@PE-1> show route table ISP1.inet.0

user@PE-1> configure

[edit]
user@PE-1# show routing-instances
ISP1 {
  instance-type forwarding;
  routing-options {
    static {
      route 0.0.0.0/0 next-hop 203.0.113.2;
    }
  }
  instance-import ISP1-import;
}

[edit]
user@PE-1# show policy-options
policy-statement ISP1-import {
  from instance inet;
  then accept;
}

```

The `isp1_inet.0` route table has currently no routes in it.

What will happen when you commit the configuration shown on the exhibit?

- A. The `inet.0` route table will be completely overwritten by the `isp1_inet.0` route table.
- B. The `inet.0` route table will be imported into the `isp1_inet.0` route table.
- C. The `ISP1_inet.0` route table will be completely overwritten by the `inet.0` route table.
- D. The `ISP1_inet.0` route table will be imported into the `inet.0` route table.

Answer: B

Explanation:

The configuration shown in the exhibit is an example of a routing instance of type virtual-router. [A routing instance is a collection of routing tables, interfaces, and routing protocol parameters that create a separate routing domain on a Juniper device1. A virtual-router routing instance allows administrators to divide a device into multiple independent virtual routers, each with its own routing table2.](#)

The configuration also includes a `rib-group` statement, which is used to import routes from one routing table to another. A `rib-group` consists of an `import-rib` statement, which specifies the source routing table, and an `export-rib` statement, which specifies the destination routing table.

In this case, the `rib-group` name is `inet-to-isp1`, and the `import-rib` statement specifies `inet.0` as the

source routing table. The export-rib statement specifies ispi.inet.0 as the destination routing table. This means that the routes from inet.0 will be imported into ispi.inet.0. Therefore, the correct answer is B. The inet.0 route table will be imported into the ispi.inet.0 route table.

Question: 5

Which statement is correct about graceful Routing Engine switchover (GRES)?

- A. The PFE restarts and the kernel and interface information is lost.
- B. GRES has a helper mode and a restarting mode.
- C. When combined with NSR, routing is preserved and the new master RE does not restart rpd.
- D. With no other high availability features enabled, routing is preserved and the new master RE does not restart rpd.

Answer: C

Explanation:

[The Graceful Routing Engine Switchover \(GRES\) feature in Junos OS enables a router with redundant Routing Engines to continue forwarding packets, even if one Routing Engine fails¹. GRES preserves interface and kernel information, ensuring that traffic is not interrupted¹. However, GRES does not preserve the control plane¹.](#)

[To preserve routing during a switchover, GRES must be combined with either Graceful Restart protocol extensions or Nonstop Active Routing \(NSR\)¹. When GRES is combined with NSR, nearly 75 percent of line rate worth of traffic per Packet Forwarding Engine remains uninterrupted during GRES¹. Any updates to the primary Routing Engine are replicated to the backup Routing Engine as soon as they occur¹.](#)

[Therefore, when GRES is combined with NSR, routing is preserved and the new master RE does not restart rpd¹.](#)
